

Aquarium Ecosystem

**What are the roles
of the bacteria
in aquariums?**

Bacteria culture is essential for aquarium creatures to survive. Bacteria that reproduce thanks to this culture consume ammonia in the aquarium and feed.

Ammonia is broken down and destroyed by these bacteria. Otherwise, the fish will be poisoned. For this reason, people often do not know the causes of death of their fish.

The bacteria culture will start to hold and reproduce in the filter at the first stage, so people should not clean the filter in the first stages. This is one of the most common mistakes aquarium users make, as cleaning filters often kills beneficial bacteria.
